

0.

填写完已有实验，执行结果如下：

```
QEMU
memory: 07efe000, [00100000, 07ffdfff], type = 1.
memory: 00002000, [07ffe000, 07ffffff], type = 2.
memory: 00040000, [fffc0000, ffffffff], type = 2.
check_alloc_page() succeeded!
check_pgdir() succeeded!
check_boot_pgdir() succeeded!
----- BEGIN -----
PDE(0e0) c0000000-f8000000 38000000 urw
!-- PTE(38000) c0000000-f8000000 38000000 -rw
PDE(001) fac00000-fb000000 00400000 -rw
!-- PTE(000e0) faf00000-fafe0000 000e0000 urw
!-- PTE(00001) fafeb000-fafec000 00001000 -rw
----- END -----
use SLOB allocator
kmalloc_init() succeeded!
check_vma_struct() succeeded!
page fault at 0x00000100: K/W [no page found].
check_pgfault() succeeded!
check_vmm() succeeded.
kernel panic at kern/process/proc.c:353:
  create init_main failed.

Welcome to the kernel debug monitor!!
Type 'help' for a list of commands.
K>
```

发现程序挂在kern/process/proc.c中，正好就是练习1中需要填充的函数对应的文件。

1.

首先查看注释：

```
* below fields in proc_struct need to be initialized
*   enum proc_state state;           // Process state
*   int pid;                         // Process ID
*   int runs;                        // the running times of Proces
*   uintptr_t kstack;               // Process kernel stack
*   volatile bool need_resched;      // bool value: need to be rescheduled to release
```

CPU?

```
*   struct proc_struct *parent;      // the parent process
*   struct mm_struct *mm;            // Process's memory management field
*   struct context context;          // Switch here to run process
*   struct trapframe *tf;            // Trap frame for current interrupt
*   uintptr_t cr3;                   // CR3 register: the base addr of Page Directroy
```

Table(PDT)

```
*   uint32_t flags;                  // Process flag
*   char name[PROC_NAME_LEN + 1];    // Process name
```

按照注释的顺序来依次初始化各变量：

由于大多数变量只需要初始化为0，故可调用memset来统一清零，再对个别进行设置。

清零后，首先是设置state，找到定义：

// process's state in his life cycle

```
enum proc_state {
    PROC_UNINIT = 0, // uninitialized
    PROC_SLEEPING,  // sleeping
    PROC_RUNNABLE,  // runnable(maybe running)
    PROC_ZOMBIE,    // almost dead, and wait parent proc to reclaim his resource
};
```

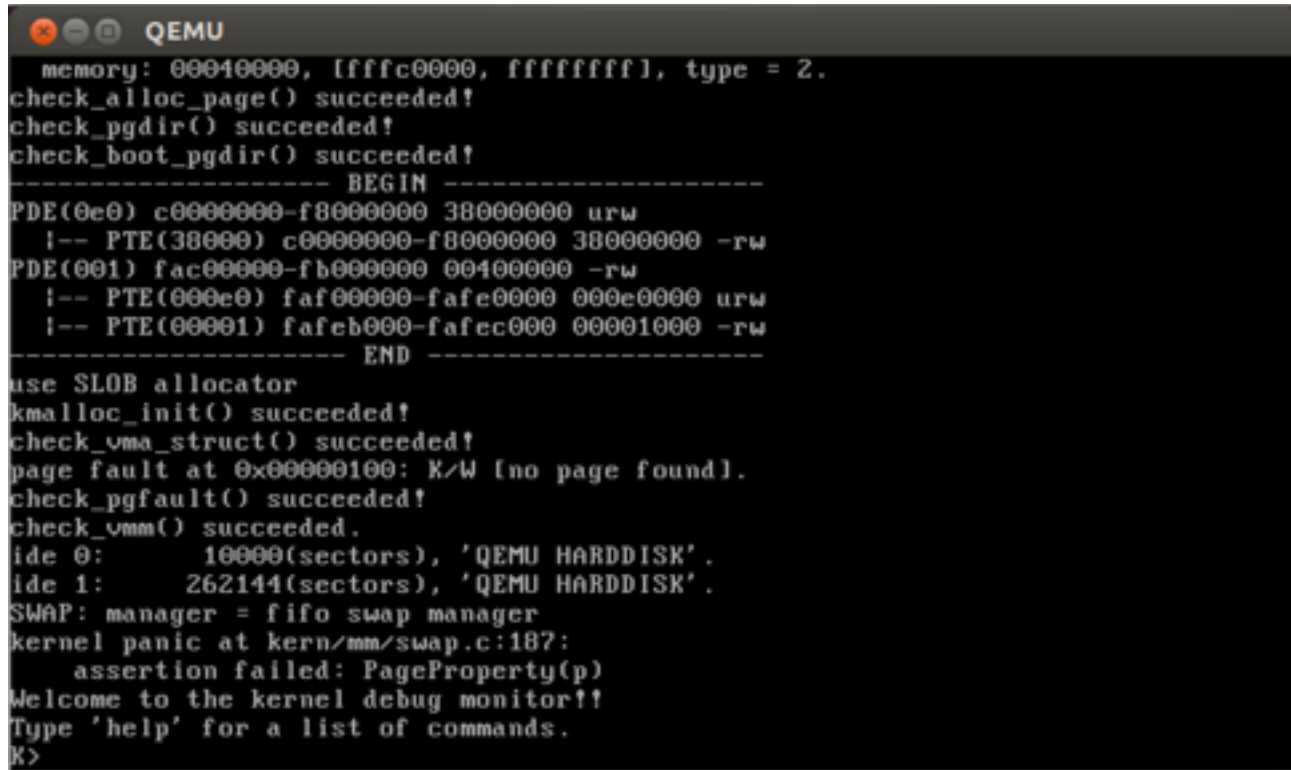

则此处应为PROC\_UNINIT；

接着是pid设为-1，最后将cr3设为内核页目录表boot\_cr3。  
全部设置完成后，再执行程序，发现执行结果并无变化（除错误行号）。

2.

按照注释的7步，一步步的翻译，需要注意的是前3步失败后要相应的跳转到对应的位置清除已分配的内存并退出。

可却得到如下结果：

```
QEMU
memory: 00040000, [ffffc0000, ffffffff], type = 2.
check_alloc_page() succeeded!
check_pgdir() succeeded!
check_boot_pgdir() succeeded!
----- BEGIN -----
PDE(0e0) c0000000-f8000000 38000000 urw
!-- PTE(38000) c0000000-f8000000 38000000 -rw
PDE(001) fac00000-fb000000 00400000 -rw
!-- PTE(000e0) faf00000-fafec000 000e0000 urw
!-- PTE(00001) fafeb000-fafec000 00001000 -rw
----- END -----
use SLOB allocator
kmalloc_init() succeeded!
check_vma_struct() succeeded!
page fault at 0x00000100: K/W [no page found].
check_pgfault() succeeded!
check_vmm() succeeded.
ide 0: 10000(sectors), 'QEMU HARDDISK'.

K>
```

调了好久，最后实在是不能理解，然后把lab2中的default\_init\_memmap、default\_alloc\_pages、default\_free\_pages换成标准答案里面的代码就过了，看起来是lab2中的代码有点问题，简直了：

```
make qemu
knalloc_init() succeeded!
check_vma_struct() succeeded!
page fault at 0x00000100: K/W [no page found].
check_pgfault() succeeded!
check_vmm() succeeded.

```

3.

proc\_run首先判断当前运行的线程是否是要切换到的线程，是则不用切换了。

然后屏蔽中断，以防止在线程切换过程中被中断而出现问题。

接着，将任务状态栈ts中的内核栈指针esp0设置好，然后将页目录表加载到cr3中，完成页表切换，最后再调用switch\_to实现线程上下文的切换，此时所有的切换操作已经准备好，只需要恢复中断即可完成进程切换。

而switch\_to所实现的就是，先将原线程执行时的各个寄存器保存到原线程的content的相应位置，然后再将新线程的content中的值恢复到各寄存器中，实现线程上下文的切换。
